Key words:
spontaneous coronary artery dissection, Loeys-Dietz syndrome, computed tomography

Loeys-Dietz syndrome is an autosomal dominant disorder affecting the connective tissue. It is generally characterized by aortic aneurysms, arterial tortuosity and dissections, hypertelorism, bifid/broad uvula or cleft palate and early-onset osteoarthritis. It is now estimated that spontaneous coronary artery dissection (SCAD) is the underlying cause of 1.7% to 4% of acute coronary syndromes (ACS) and accounts for 0.5% of sudden cardiac deaths. Furthermore, in young women <60 years of age, SCAD accounts for 22% to 35% of ACS presentations. It has been proposed that a mutation in transforming growth factor beta receptors 1 and 2 and SMAD3 genes and a documented arterial aneurysm or dissection should suffice to establish a diagnosis of LDS. A 48-year-old woman with Loeys-Dietz syndrome with no aortic enlargement was admitted for scheduled diagnostics for examination of coronaries due to nonspecific chest pain. The 12-lead ECG recorded at rest suggested myocardial necrosis of both anterior and inferior regions of the left ventricle. Echocardiography revealed mild enlargement of the left ventricle with its hypertrophy and aneurysm of the inferior wall and apical akinesia. The ECG-gated 384-row angio-CT (SOMATOM, Siemens Healthineers, Erlangen, Germany) revealed presence of dissection of the tunica intima suggesting features of SCAD recognized along the entire lengths of proximal segments of the right coronary (RCA) and the left anterior descending artery (LAD) (Figure 1a, 1b and 2a, 2b; respectively). Finally, digital coronarography was performed using the Siemens AXIOM (1024x1024 flat panel detector) that confirmed typical features of SCAD which did not interfere with epicardial blood and tissue blood flow (normal TIMI epicardial and myocardial blood flow).
(Figure 3a, 3b; respectively). After initiation of the optimal medical therapy, the patient was discharged with no symptoms and was scheduled for routine angiography at 12-month follow-up, or whenever symptoms of angina pectoris reoccur. Spontaneous coronary artery dissection is a rare complication in patients with Loeys-Dietz syndrome that can appear due to malformation of the connective tissue in the lining of the coronary arteries. Missed diagnoses are caused by both visual limitations of current CT and lack of clinician familiarity with the condition. The 1024x1024 digital coronarography (Figure 1; 1.a, 1.b, 2.a, 2.b) is a rarely used screening method. The case highlights the importance of proper angiographic screening in patients with Loeys-Dietz syndrome, especially in young females, and proves that digital coronarography is a viable method of SCAD screening.
SCAD of coronaries in the course of Loeys-Dietz syndrome
